HIGH-SPEED GENERAL PURPOSE RADIOGRAPHIC FILM

FIELD OF THE INVENTION

This invention is directed to radiography. In particular, it is
5 directed to a high-speed radiographic silver halide film that provides improved
medical diagnostic images for general radiography.

BACKGROUND OF THE INVENTION

In conventional medical diagnostic imaging, the object is to obtain
10 an image of a patient's internal anatomy with as little X-radiation exposure as
possible. The fastest imaging speeds are realized by mounting a dual-coated
radiographic element between a pair of fluorescent intensifying screens for
imagewise exposure. About 5% or less of the exposing X-radiation passing
through the patient is adsorbed directly by the latent image forming silver halide
15 emulsion layers within the dual-coated radiographic element. Most of the X-
radiation that participates in image formation is absorbed by phosphor particles
within the fluorescent screens. This stimulates light emission that is more readily
absorbed by the silver halide emulsion layers of the radiographic element.

Examples of radiographic element constructions for medical
20 diagnostic purposes are provided by U. S. Patent 4,425,425 (Abbott et al.) and
U.S. Patent 4,425,426 (Abbott et al.), U.S. Patent 4,414,310 (Dickerson), U.S.
Patent 4,803,150 (Dickerson et al.), U.S. Patent 4,900,652 (Dickerson et al.), U.S.
Patent 5,252,442 (Tsaur et al.), U.S. Patent 5,576,156 (Dickerson), and *Research*
Disclosure, Vol. 184, August 1979, Item 18431.

25

Problem to be Solved

Image quality and radiation dosage are two important features of
film-screen radiographic combinations (or imaging assemblies). High image
quality (that is, high resolution or sharpness) is of course desired, but there is also
30 the desire to minimize exposure of patients to radiation. Thus, "high speed"
radiographic films are needed. However, in known radiographic films, the two

features generally go in opposite directions. Thus, films that can be used with low radiation dosages (that is, "high speed" assemblies) generally provide images with poorer image quality (poorer resolution). Lower speed imaging assemblies generally require higher radiation dosages.

5 There is a need for films for general-purpose radiography that require minimum radiation dosages with minimal sacrifice in image quality (such as resolution or sharpness).

SUMMARY OF THE INVENTION

10 This invention provides a symmetric radiographic silver halide film having a film speed of at least 700, and comprising a support that has first and second major surfaces and that is capable of transmitting X-radiation,

 the radiographic silver halide film having disposed on the first major support surface, two or more hydrophilic colloid layers including first and second silver halide emulsion layers, and having on the second major support surface, two or more hydrophilic colloid layers including third and fourth silver halide emulsion layers, the first and third silver halide emulsion layers being the outermost emulsion layers on their respective sides of the support,

 each of the first, second, third, and fourth silver halide emulsion layers comprising tabular silver halide grains that have the same or different composition, an aspect ratio of at least 15, and an average grain diameter of at least 3.0 μm and comprise at least 90 mol % bromide and up to 3 mol % iodide, both based on total silver in the grains,

 the second and fourth silver halide emulsion layers comprising a crossover control agent sufficient to reduce crossover to less than 10%,

 wherein the tabular silver halide grains in the second and fourth silver halide emulsion layers are dispersed in a hydrophilic polymeric vehicle mixture comprising at least 0.25% of oxidized gelatin, based on the total dry weight of the hydrophilic polymeric vehicle mixture.

30 In preferred embodiments, this invention provides a symmetric radiographic silver halide film having a film speed of at least 800, and comprising

a support that has first and second major surfaces and that is capable of transmitting X-radiation,

the radiographic silver halide film having disposed on said first major support surface, two or more hydrophilic colloid layers including first and second silver halide emulsion layers, and having on the second major support surface, two or more hydrophilic colloid layers including third and fourth silver halide emulsion layers, the first and third silver halide emulsion layers being the outermost emulsion layers on their respective sides of the support,

each of the first and third silver halide emulsion layers comprising tabular silver halide grains that have the same composition, an aspect ratio of from about 15 to about 25, an average grain diameter of at least $4.0\text{ }\mu\text{m}$, an average thickness of from about $0.12\text{ }\mu\text{m}$ to about $0.13\text{ }\mu\text{m}$, and comprise at least 98 mol % bromide and up to 0.5 mol % iodide, both based on total silver in the grains,

each of the second and fourth silver halide emulsion layers comprising tabular silver halide grains that have the same composition, an aspect ratio of from about 38 to about 45, an average thickness of from about $0.09\text{ }\mu\text{m}$ to about $0.11\text{ }\mu\text{m}$, and comprise at least 98 mol % bromide and up to 0.5 mol % iodide, both based on total silver in the grains,

each of the second and fourth silver halide emulsion layers comprising a particulate oxonol dye as a crossover control agent present in an amount of from about 1 to about 1.3 mg/dm^2 that is sufficient to reduce crossover to less than 8% and that is decolorized during development within 45 seconds,

the film further comprising a protective overcoat on both sides of said support disposed over all of the hydrophilic colloid layers,

wherein the tabular silver halide grains in the second and fourth silver halide emulsion layers are dispersed in a hydrophilic polymeric vehicle mixture comprising from about 0.3 to about 1.5% of deionized oxidized gelatin, based on the total dry weight of the hydrophilic polymeric vehicle mixture,

wherein the dry, unprocessed thickness ratio of the first silver halide emulsion layer to that of the second silver halide emulsion layer is from about 3:1 to about 1:1, and the dry, unprocessed thickness ratio of the third silver

halide emulsion layer to that of the fourth silver halide emulsion layer is independently from about 3:1 to about 1:1, and

wherein the molar ratio of silver in the first silver halide emulsion layer to that of the second silver halide emulsion layer is from about 1.5:1 to about 3:1, and the molar ratio of silver in the third silver halide emulsion layer to that of the fourth silver halide emulsion layer is independently from about 1.5:1 to about 3:1.

This invention also provides a radiographic imaging assembly comprising a radiographic silver halide film of this invention that is arranged in association with one or more fluorescent intensifying screens. In preferred embodiments, the radiographic silver halide films of this invention are arranged in association with two fluorescent intensifying screens, one on either side thereof.

In addition, a method of providing a black-and-white image comprises exposing a radiographic silver halide film of the present invention and processing it, sequentially, with a black-and-white developing composition and a fixing composition, the processing being carried out within 90 seconds, dry-to-dry. The resulting images can be used for a medical diagnosis. The film can be imaged within the imaging assembly of this invention or outside of it.

The present invention provides a film useful for providing general purpose radiographic images having improved image quality (resolution or sharpness) while imaging X-radiation dosage can be reduced.

In addition, the radiographic films have higher D_{\max} , increased speed (at least 700) and contrast, and decreased D_{\min} (fog). In addition, the radiographic film can be rapidly processed in conventional processing equipment and compositions.

These advantages are achieved by having a unique set of two silver halide emulsion layers on both sides of the film support comprising tabular silver halide grains having specific halide compositions and aspect ratios. In addition, the silver halide emulsion layers closest to the support on both sides comprise crossover control agents and their tabular grains are dispersed in a polymeric

binder mixture that includes at least 0.25 weight % of oxidized gelatin (based on total dry weight of the polymeric binder mixture.

DETAILED DESCRIPTION OF THE INVENTION

5 Definition of Terms:

The term "contrast" as herein employed indicates the average contrast derived from a characteristic curve of a radiographic film using as a first reference point (1) a density (D_1) of 0.25 above minimum density and as a second reference point (2) a density (D_2) of 2.0 above minimum density, where contrast is

10 ΔD (i.e. 1.75) $\div \Delta \log_{10} E$ ($\log_{10} E_2 - \log_{10} E_1$), E_1 and E_2 being the exposure levels at the reference points (1) and (2).

"Gamma" is described as the instantaneous rate of change of a D $\log E$ sensitometric curve or the instantaneous contrast at any $\log E$ value.

The term "dual-coated" is used to define a radiographic film

15 having silver halide emulsion layers disposed on both the front- and backsides of the support. The radiographic silver halide films of the present invention are "dual-coated."

The radiographic films of the present invention are "symmetric" films wherein the silver halide emulsion layers on each side of the support are

20 essentially the same (no compositional differences that provide significant coating or imaging differences).

"Crossover" measurements for "symmetric" radiographic silver halide films of the present invention are obtained by determining the density of the silver developed on each side of the support, both adjacent the intensifying screen

25 and on the opposing side of the support. Densities can be determined using a standard densitometer. By plotting the density produced on each side versus the steps of a conventional step wedge (a measure of exposure), a characteristic sensitometric curve is generated for each side. A higher density is produced for a given exposure of a silver halide emulsion layer that is adjacent the film support.

30 Thus, the two sensitometric curves are offset in speed. At three different density levels in the relatively straight-line portions of the sensitometric curves between

the toe and shoulder regions of the curves, the difference in speed ($\Delta \log E$) between the two sensitometric curves is measured. These differences were then averaged and used in the following equation to calculate the % crossover:

$$\% \text{ Crossover} = \frac{1}{\text{antilog}(\Delta \log E) + 1} \times 100$$

The term "rapid access processing" is employed to indicate dry-to-dry processing of a radiographic film in 45 seconds or less. That is, 45 seconds or less elapse from the time a dry imagewise exposed radiographic film enters a wet processor until it emerges as a dry fully processed film.

In referring to grains and silver halide emulsions containing two or more halides, the halides are named in order of ascending molar concentrations.

The term "equivalent circular diameter" (ECD) is used to define the diameter of a circle having the same projected area as a silver halide grain. This can be measured using known techniques.

The term "aspect ratio" is used to define the ratio of grain ECD to grain thickness.

The term "coefficient of variation" (COV) is defined as 100 times the standard deviation (a) of grain ECD divided by the mean grain ECD.

The term "fluorescent intensifying screen" refers to a screen that absorbs X-radiation and emits light. A "prompt" emitting fluorescent intensifying screen will emit light immediately upon exposure to radiation while "storage" fluorescent screen can "store" the exposing X-radiation for emission at a later time when the screen is irradiated with other radiation (usually visible light).

The terms "front" and "back" refer to layers, films, or fluorescent intensifying screens nearer to and farther from, respectively, the source of X-radiation.

Research Disclosure is published by Kenneth Mason Publications, Ltd., Dudley House, 12 North St., Emsworth, Hampshire P010 7DQ England. The

publication is also available from Emsworth Design Inc., 147 West 24th Street, New York, N.Y. 10011.

Radiographic Films

5 The radiographic silver halide films of this invention include a flexible support having disposed on both sides thereof, two or more photographic silver halide emulsion (hydrophilic colloid) layers and optionally one or more non-radiation sensitive hydrophilic colloid layer(s). Thus, the “first” and “second” silver halide emulsion layers are considered to be disposed
10 on the frontside of the support and the “third” and “fourth” silver halide emulsion layers are considered to be disposed on the backside of the support, with the second and fourth silver halide emulsion layers being closer to the support (innermost silver halide emulsion layers) than the first and third silver halide emulsion layers (outermost silver halide emulsion layers).

15 In preferred embodiments, the photographic silver halide film has two different silver halide emulsion layers on each side of the support and a protective overcoat (described below) over both silver halide emulsion layers on each side of the support. Thus, the first and second silver halide emulsion layers are different and the third and fourth silver halide emulsion layers are different.
20 However, the first and third silver halide emulsion layers have essentially the same composition (for example, components, types of grains, silver halide composition, hydrophilic colloid binder composition, g/m^2 coverage), and the second and fourth silver halide emulsion layers have essentially the same composition (for example, components, types of grains, silver halide
25 composition, hydrophilic colloid binder composition, g/m^2 coverage).

 The support can take the form of any conventional radiographic film support that is X-radiation and light transmissive. Useful supports for the films of this invention can be chosen from among those described in *Research Disclosure*, September 1996, Item 38957 XV. Supports and *Research Disclosure*, Vol. 184, August 1979, Item 18431, XII. Film Supports. The
30 support is preferably a transparent film support. In its simplest possible form the

transparent film support consists of a transparent film chosen to allow direct adhesion of the hydrophilic silver halide emulsion layers or other hydrophilic layers. More commonly, the transparent film is itself hydrophobic and subbing layers are coated on the film to facilitate adhesion of the hydrophilic silver halide emulsion layers. Typically the film support is either colorless or blue tinted (tinting dye being present in one or both of the support film and the subbing layers). Polyethylene terephthalate and polyethylene naphthalate are the preferred transparent film support materials.

In the more preferred embodiments, at least one non-light sensitive hydrophilic layer is included with the one or more silver halide emulsion layers on each side of the film support. This layer may be an interlayer or overcoat, or both types of non-light sensitive layers can be present.

The first, second, third, and fourth silver halide emulsion layers comprise predominantly (more than 50 %, and preferably at least 70%, of the total grain projected area) tabular silver halide grains. The grain composition can vary among the layers, but preferably, the grain composition is essentially the same in the first and third silver halide emulsion layers and independently, it is essentially the same in the second and fourth silver halide emulsion layers. These tabular silver halide grains generally comprise at least 90, preferably at least 95, and more preferably at least 98, mol % bromide, based on total silver in the emulsion layer. Such emulsions include silver halide grains composed of, for example, silver iodobromide, silver chlorobromide, silver iodochlorobromide, and silver chloriodobromide. The iodide grain content is generally up to 3 mol %, based on total silver in the emulsion layer. Preferably the iodide grain content is up to 2 mol %, and more preferably up to about 0.5 mol % (based on total silver in the emulsion layer). Mixtures of different tabular silver halide grains can be used in any of the silver halide emulsion layers.

Any of the silver halide emulsion layers can also include some non-tabular silver halide grains having any desirable non-tabular or be comprised of a mixture of two or more of such morphologies. The composition and methods of making such silver halide grains are well known in the art.

The tabular silver halide grains used in the first and third silver halide emulsion layers generally have an aspect ratio of 15 or more, and preferably from about 15 to about 25. The aspect ratio can be the same or different in the two silver halide emulsion layers.

5 Moreover, the tabular silver halide grains in the second and fourth silver halide emulsion layers generally have an aspect ratio of 35 or more, and preferably from about 38 to about 45.

 In general, the tabular grains in any of the silver halide emulsion layers have an average grain diameter (ECD) of at least 3.0 μm , and preferably of
10 at least 4.0 μm . The average grain diameters can be the same or different in the various emulsion layers. At least 100 non-overlapping tabular grains are measured to obtain the "average" ECD.

 In addition, the tabular grains in the first and third silver halide emulsion layers generally have an average thickness of from about 0.11 to about
15 0.14 μm , and preferably from about 0.12 to about 0.13 μm . The tabular grains in the second and fourth silver halide emulsion layers generally have an average thickness of from about 0.08 to about 0.12 μm , and preferably from about 0.09 to about 0.11 μm .

 The procedures and equipment used to determine tabular grain size
20 (and aspect ratio) are well known in the art.

 Tabular grain emulsions that have the desired composition and sizes are described in greater detail in the following patents, the disclosures of which are incorporated herein by reference:

 U. S. Patent 4,414,310 (Dickerson), U.S. Patent 4,425,425 (Abbott
25 et al.), U.S. Patent 4,425,426 (Abbott et al.), U.S. Patent 4,439,520 (Kofron et al.), U.S. Patent 4,434,226 (Wilgus et al.), U.S. Patent 4,435,501 (Maskasky), U.S. Patent 4,713,320 (Maskasky), U.S. Patent 4,803,150 (Dickerson et al.), U.S. Patent 4,900,355 (Dickerson et al.), U.S. Patent 4,994,355 (Dickerson et al.), U.S. Patent 4,997,750 (Dickerson et al.), U.S. Patent 5,021,327 (Bunch et al.), U.S.
30 Patent 5,147,771 (Tsaur et al.), U.S. Patent 5,147,772 (Tsaur et al.), U.S. Patent 5,147,773 (Tsaur et al.), U.S. Patent 5,171,659 (Tsaur et al.), U.S. Patent

5,252,442 (Dickerson et al.), U.S. Patent 5,370,977 (Zietlow), U.S. Patent 5,391,469 (Dickerson), U.S. Patent 5,399,470 (Dickerson et al.), U.S. Patent 5,411,853 (Maskasky), U.S. Patent 5,418,125 (Maskasky), U.S. Patent 5,494,789 (Daubendiek et al.), U.S. Patent 5,503,970 (Olm et al.), U.S. Patent 5,536,632 (Wen et al.), U.S. Patent 5,518,872 (King et al.), U.S. Patent 5,567,580 (Fenton et al.), U.S. Patent 5,573,902 (Daubendiek et al.), U.S. Patent 5,576,156 (Dickerson), U.S. Patent 5,576,168 (Daubendiek et al.), U.S. Patent 5,576,171 (Olm et al.), and U.S. Patent 5,582,965 (Deaton et al.).

The silver halide emulsion layers on opposite sides of the support can have the same general dry unprocessed thickness and coating weight, but preferably, the two silver halide emulsion layers on each side have different dry thickness. It is preferable that the outermost silver halide emulsion layers be thicker than the silver halide emulsion layers closer to the support. These evaluations are made on the dried film before it is contacted with processing solutions. Thus, the dry, unprocessed thickness ratio of the first silver halide emulsion layer to that of the second silver halide emulsion layer is greater than 1:1 (preferably from about 3:1 to about 1:1), and the dry, unprocessed thickness ratio of the third silver halide emulsion layer to that of the fourth silver halide emulsion layer is independently greater than 1:1 (preferably from about 3:1 to about 1:1).

In addition, the silver halide emulsion layers closer to the support on both sides (that is the second and fourth silver halide emulsion layers) comprise one or more "crossover control agents" that are present in sufficient amounts to reduce light transmitted through the support to opposing layers to less than 10% and preferably less than 8%. Crossover is measured in the practice of this invention as noted above.

Useful crossover control agents are well known in the art and include one or more compounds that provide a total density of at least 0.3 (preferably at least 0.45) and up to 0.9 at a preferred wavelength of 545 nm and that are disposed on a transparent support. The density can be measured using a standard densitometer (using "visual status"). In general, the amount of crossover control agent in the "second" silver halide emulsion layer will vary depending

upon the strength of absorption of the given compound(s), but for most pigments and dyes, the amount is generally from about 0.75 to about 1.5 mg/dm² (preferably from about 1 mg to about 1.3 mg/dm²).

In addition, the crossover control agents must be substantially
5 removed within 90 seconds (preferably with 45 seconds) during processing (generally during development). By "substantially" means that the crossover control agent remaining in the film after processing provides no more than 0.05 optical density as measured using a conventional sensitometer. Removal of the crossover control agents can be achieved by their migration out of the film, but
10 preferably, they are not physically removed but are decolorized during processing.

Pigments and dyes that can be used as crossover control agents include various water-soluble, liquid crystalline, or particulate magenta or yellow filter dyes or pigments including those described for example in U.S. Patent 4,803,150 (Dickerson et al.), U.S. Patent 5,213,956 (Diehl et al.), U.S. Patent
15 5,399,690 (Diehl et al.), U.S. Patent 5,922,523 (Helber et al.), U.S. Patent 6,214,499 (Helber et al.), and Japanese Kokai 2-123349, all of which are incorporated herein by reference for pigments and dyes useful in the practice of this invention. One useful class of particulate dyes useful as crossover control agents includes nonionic polymethine dyes such as merocyanine, oxonol,
20 hemioxonol, styryl, and arylidene dyes as described in U.S. Patent 4,803,150 (noted above) that is incorporated herein for the definitions of those dyes. The particulate magenta merocyanine and oxonol dyes are preferred and the particulate magenta oxonol dyes are most preferred.

One particularly useful magenta oxonol dye that can be used as a
25 crossover control agent is the following compound M-1:

M-1

5

A variety of silver halide dopants can be used, individually and in combination, in one or more of the silver halide emulsion layers to improve contrast as well as other common sensitometric properties. A summary of conventional dopants is provided by *Research Disclosure*, Item 38957, cited above, Section I. Emulsion grains and their preparation, sub-section D. Grain modifying conditions and adjustments, paragraphs (3), (4), and (5).

A general summary of silver halide emulsions and their preparation is provided by *Research Disclosure*, Item 38957, cited above, Section I. Emulsion grains and their preparation. After precipitation and before chemical sensitization the emulsions can be washed by any convenient conventional technique using techniques disclosed by *Research Disclosure*, Item 38957, cited above, Section III. Emulsion washing.

Any of the emulsions can be chemically sensitized by any convenient conventional technique as illustrated by *Research Disclosure*, Item 38957, Section IV. Chemical Sensitization: Sulfur, selenium or gold sensitization (or any combination thereof) is specifically contemplated. Sulfur sensitization is preferred, and can be carried out using for example, thiosulfates, thiosulfonates, thiocyanates, isothiocyanates, thioethers, thioureas, cysteine, or rhodanine. A combination of gold and sulfur sensitization is most preferred.

In addition, if desired, any of the silver halide emulsions can include one or more suitable spectral sensitizing dyes that include, for example, cyanine and merocyanine spectral sensitizing dyes. The useful amounts of such dyes are well known in the art but are generally within the range of from about
5 200 to about 1000 mg/mole of silver in the given emulsion layer. It is particularly preferred that all of the tabular silver halide grains used in the present invention (in all silver halide emulsion layers) be "green-sensitized", that is spectrally sensitized to radiation of from about 470 to about 570 nm of the electromagnetic spectrum. Various spectral sensitizing dyes are known for achieving this
10 characteristic.

Instability that increases minimum density in negative-type emulsion coatings (that is fog) can be protected against by incorporation of stabilizers, antifoggants, antikinking agents, latent-image stabilizers and similar addenda in the emulsion and contiguous layers prior to coating. Such addenda are
15 illustrated by *Research Disclosure*, Item 38957, Section VII. Antifoggants and stabilizers, and Item 18431, Section II: Emulsion Stabilizers, Antifoggants and Antikinking Agents.

It may also be desirable that one or more silver halide emulsion layers include one or more covering power enhancing compounds adsorbed to
20 surfaces of the silver halide grains. A number of such materials are known in the art, but preferred covering power enhancing compounds contain at least one divalent sulfur atom that can take the form of a -S- or =S moiety. Such compounds are described in U.S. Patent 5,800,976 (Dickerson et al.) that is incorporated herein by reference for the teaching of such sulfur-containing
25 covering power enhancing compounds.

The silver halide emulsion layers and other hydrophilic layers on both sides of the support of the radiographic films of this invention generally contain conventional polymer vehicles (peptizers and binders) that include both synthetically prepared and naturally occurring colloids or polymers. The most
30 preferred polymer vehicles include gelatin or gelatin derivatives alone or in combination with other vehicles. Conventional gelatino-vehicles and related layer

features are disclosed in *Research Disclosure*, Item 38957, Section II. Vehicles, vehicle extenders, vehicle-like addenda and vehicle related addenda. The emulsions themselves can contain peptizers of the type set out in Section II, paragraph A. Gelatin and hydrophilic colloid peptizers. The hydrophilic colloid peptizers are also useful as binders and hence are commonly present in much higher concentrations than required to perform the peptizing function alone. The preferred gelatin vehicles include alkali-treated gelatin, acid-treated gelatin or gelatin derivatives (such as acetylated gelatin, deionized gelatin, oxidized gelatin and phthalated gelatin). Cationic starch used as a peptizer for tabular grains is described in U.S. Patent 5,620,840 (Maskasky) and U.S. Patent 5,667,955 (Maskasky). Both hydrophobic and hydrophilic synthetic polymeric vehicles can be used also. Such materials include, but are not limited to, polyacrylates (including polymethacrylates), polystyrenes and polyacrylamides (including polymethacrylamides). Dextrans can also be used. Examples of such materials are described for example in U.S. Patent 5,876,913 (Dickerson et al.), incorporated herein by reference.

Thin, high aspect ratio tabular grain silver halide emulsions useful in the present invention will typically be prepared by processes including nucleation and subsequent growth steps. During nucleation, silver and halide salt solutions are combined to precipitate a population of silver halide nuclei in a reaction vessel. Double jet (addition of silver and halide salt solutions simultaneously) and single jet (addition of one salt solution, such as a silver salt solution, to a vessel already containing an excess of the other salt) process are known. During the subsequent growth step, silver and halide salt solutions, and/or preformed fine silver halide grains, are added to the nuclei in the reaction vessel, and the added silver and halide combines with the existing population of grain nuclei to form larger grains. Control of conditions for formation of high aspect ratio tabular grain silver bromide and iodobromide emulsions is known, e.g., based upon (Wilgus et al.) U.S. Patent No. 4,434,226, (Solberg et al.) U.S. Patent No. 4,433, 048 and (Kofron et al.) U.S. Patent No. 4,439,520. It is recognized, e.g., that the bromide ion concentration in solution at the stage of

grain formation must be maintained within limits to achieve the desired tabularity of grains. As grain growth continues, the bromide ion concentration in solution becomes progressively less influential on the grain shape ultimately achieved. For example, Wilgus et al U.S. Patent No. 4,434,226, e.g., teaches the precipitation of high aspect ratio tabular grain silver bromiodide emulsions at bromide ion concentrations in the pBr range of from 0.6 to 1.6 during grain nucleation, with the pBr range being expanded to 0.6 to 2.2 during subsequent grain growth. (Kofron et al.) U.S. Patent No. 4,439,520 extends these teachings to the precipitation of high aspect ratio tabular grain silver bromide emulsions. pBr is defined as the negative log of the solution bromide ion concentration. (Daubendiek et al.) U.S. Patent No. 4,414,310 describes a process for the preparation of high aspect ratio silver bromiodide emulsions under pBr conditions not exceeding the value of 1.64 during grain nucleation. (Maskasky) U.S. Pat. No. 4,713,320 in the preparation of high aspect ratio silver halide emulsions, teaches that the useful pBr range during nucleation can be extended to a value of 2.4 when the precipitation of the tabular silver bromide or bromiodide grains occurs in the presence of gelatino-peptizer containing less than 30 micromoles of methionine (e.g., oxidized gelatin) per gram. The use of such oxidized gel also enables the preparation of thinner and/or larger diameter grains, and/or more uniform grain populations containing fewer non-tabular grains.

The use of oxidized gelatin as peptizer during nucleation, such as taught by U.S. Patent No. 4,713,320, is particularly preferred for making thin, high aspect ratio tabular grain emulsions for use in the present invention, employing either double or single jet nucleation processes. As gelatin employed as peptizer during nucleation typically will comprise only a fraction of the total gelatin employed in an emulsion, the percentage of oxidized gelatin in the resulting emulsion may be relatively small, that is, at least 0.25% (based on total dry weight).

Thus it is essential that the coated second and fourth tabular grain silver halide emulsion layers, on one or both sides of the support, comprise tabular silver halide grains dispersed in a hydrophilic polymeric vehicle mixture

comprising at least 0.25% and preferably at least 0.35% of oxidized gelatin based on the total dry weight of hydrophilic polymeric vehicle mixture in that coated emulsion layer. The upper limit for the oxidized gelatin is not critical but for practical purposes it is 1.5% based on the total dry weight of the hydrophilic polymer vehicle mixture. Preferably, from about 0.4 to about 0.6% (by dry weight) of the hydrophilic polymer vehicle mixture is oxidized gelatin.

It is also preferred that the oxidized gelatin be in the form of deionized oxidized gelatin but non-deionized oxidized gelatin can be used, or a mixture of deionized and non-deionized oxidized gelatins can be used. Deionized or non-deionized oxidized gelatin generally has the property of relatively lower amounts of methionine per gram of gelatin than other forms of gelatin. Preferably, the amount of methionine is from 0 to about 3 μmol of methionine, and more preferably from 0 to 1 μmol of methionine, per gram of gelatin. This material can be prepared using known procedures.

The remainder of the polymeric vehicle mixture can be any of the hydrophilic vehicles described above, but preferably it is composed of alkali-treated gelatin, acid-treated gelatin acetylated gelatin, or phthalated gelatin.

The silver halide emulsions containing the tabular silver halide grains described above can be prepared as noted using a considerable amount of oxidized gelatin (preferably deionized oxidized gelatin) during grain nucleation and growth, and then additional polymeric binder can be added to provide the coating formulation. The amounts of oxidized gelatin in the emulsion can be as low as 0.3 g per mole of silver and as high as 27 g per mole of silver in the emulsion. Preferably, the amount of oxidized gelatin in the emulsion is from about 1 to about 20 g per mole of silver.

The silver halide emulsion layers (and other hydrophilic layers) in the radiographic films are generally fully hardened using one or more conventional hardeners. Thus, the amount of hardener on each side of the support is generally at least 1.5% and preferably at least 2%, based on the total dry weight of the polymer vehicles on each side of the support.

The levels of silver and polymer vehicle in the radiographic silver halide film of the present invention can vary in the various silver halide emulsion layers. In general, the total amount of silver on each side of the support is at least 18 and no more than 24 mg/dm². In addition, the total coverage of polymer vehicle on each side of the support is generally at least 30 and no more than 40 mg/dm². The amounts of silver and polymer vehicle on the two sides of the support in the radiographic silver halide film can be the same or different. These amounts refer to dry weights.

In addition, the molar ratio of silver in the first silver halide emulsion layer to that of the second silver halide emulsion layer is greater than 1:1 (preferably from about 1.5:1 to about 3:1), and the molar ratio of silver in the third silver halide emulsion layer to that of the fourth silver halide emulsion layer is independently greater than 1:1 (preferably from about 1.5:1 to about 3:1).

The radiographic silver halide films of this invention generally include a surface protective overcoat disposed on each side of the support that typically provides for physical protection of the various layers underneath. Each protective overcoat can be sub-divided into two or more individual layers. For example, protective overcoats can be sub-divided into surface overcoats and interlayers (between the overcoat and silver halide emulsion layers). In addition to vehicle features discussed above the protective overcoats can contain various addenda to modify the physical properties of the overcoats. Such addenda are illustrated by *Research Disclosure*, Item 38957, Section IX. Coating physical property modifying addenda, A. Coating aids, B. Plasticizers and lubricants, C. Antistats, and D. Matting agents. Interlayers that are typically thin hydrophilic colloid layers can be used to provide a separation between the silver halide emulsion layers and the surface overcoats or between the silver halide emulsion layers. The overcoat on at least one side of the support can also include a blue toning dye or a tetraazaindene (such as 4-hydroxy-6-methyl-1,3,3a,7-tetraazaindene) if desired.

The protective overcoat is generally comprised of one or more hydrophilic colloid vehicles, chosen from among the same types disclosed above in connection with the emulsion layers.

5 The various coated layers of radiographic silver halide films of this invention can also contain tinting dyes to modify the image tone to transmitted or reflected light. These dyes are not decolorized during processing and may be homogeneously or heterogeneously dispersed in the various layers. Preferably, such non-bleachable tinting dyes are in a silver halide emulsion layer.

10 **Imaging Assemblies**

The radiographic imaging assemblies of the present invention are composed of one radiographic silver halide film of this invention and one or more fluorescent intensifying screens. Usually, two fluorescent intensifying screen are used, one on the "frontside" and the other on the "backside" of the film.

15 Fluorescent intensifying screens are typically designed to absorb X-rays and to emit electromagnetic radiation having a wavelength greater than 300 nm. These screens can take any convenient form providing they meet all of the usual requirements for use in radiographic imaging. Examples of conventional, useful fluorescent intensifying screens are provided by *Research Disclosure*, Item 18431, cited above, Section IX. X-Ray Screens/Phosphors, and U.S. Patent 5,021,327 (Bunch et al.), U.S. Patent 4,994,355 (Dickerson et al.), U.S. Patent 4,997,750 (Dickerson et al.), and U.S. Patent 5,108,881 (Dickerson et al.), the disclosures of which are here incorporated by reference. The fluorescent layer contains phosphor particles and a binder, optimally additionally containing a light scattering material,

20 such as titania.

Any conventional or useful phosphor can be used, singly or in mixtures, in the intensifying screens used in the practice of this invention. For example, useful phosphors are described in numerous references relating to fluorescent intensifying screens, including but not limited to, *Research Disclosure*,

30 Vol. 184, August 1979, Item 18431, Section IX, X-ray Screens/Phosphors, and U.S. Patent 2,303,942 (Wynd et al.), U.S. Patent 3,778,615 (Luckey), U.S. Patent

4,032,471 (Luckey), U.S. Patent 4,225,653 (Brixner et al.), U.S. Patent 3,418,246 (Royce), U.S. Patent 3,428,247 (Yocon), U.S. Patent 3,725,704 (Buchanan et al.), U.S. Patent 2,725,704 (Swindells), U.S. Patent 3,617,743 (Rabatin), U.S. Patent 3,974,389 (Ferri et al.), U.S. Patent 3,591,516 (Rabatin), U.S. Patent 3,607,770 (Rabatin), U.S. Patent 3,666,676 (Rabatin), U.S. Patent 3,795,814 (Rabatin), U.S. Patent 4,405,691 (Yale), U.S. Patent 4,311,487 (Luckey et al.), U.S. Patent 4,387,141 (Patten), U.S. Patent 5,021,327 (Bunch et al.), U.S. Patent 4,865,944 (Roberts et al.), U.S. Patent 4,994,355 (Dickerson et al.), U.S. Patent 4,997,750 (Dickerson et al.), U.S. Patent 5,064,729 (Zegarski), U.S. Patent 5,108,881 (Dickerson et al.), U.S. Patent 5,250,366 (Nakajima et al.), U.S. Patent 5,871,892 (Dickerson et al.), EP 0 491,116A1 (Benzo et al.), the disclosures of all of which are incorporated herein by reference with respect to the phosphors.

The silver halide film of the invention and the fluorescent intensifying screens can be arranged in a suitable "cassette" designed for this purpose and well known in the art.

Imaging and Processing

Exposure and processing of the radiographic silver halide films of this invention can be undertaken in any convenient conventional manner. The exposure and processing techniques of U.S. Patents 5,021,327 and 5,576,156 (both noted above) are typical for processing radiographic films. Other processing compositions (both developing and fixing compositions) are described in U.S. Patent 5,738,979 (Fitterman et al.), U.S. Patent 5,866,309 (Fitterman et al.), U.S. Patent 5,871,890 (Fitterman et al.), U.S. Patent 5,935,770 (Fitterman et al.), U.S. Patent 5,942,378 (Fitterman et al.), all incorporated herein by reference. The processing compositions can be supplied as single- or multi-part formulations, and in concentrated form or as more diluted working strength solutions.

Exposing X-radiation is generally directed through a patient and then through a fluorescent intensifying screen arranged against the frontside of the film before it passes through the radiographic silver halide film, and the second fluorescent intensifying screen.

It is particularly desirable that the radiographic silver halide films of this invention be processed within 90 seconds ("dry-to-dry") and preferably for at least 20 seconds and up to 60 seconds ("dry-to-dry"), including the developing, fixing, any washing (or rinsing) steps, and drying. Such processing can be carried out in any suitable processing equipment including but not limited to, a Kodak X-OMAT[®] RA 480 processor that can utilize Kodak Rapid Access processing chemistry. Other "rapid access processors" are described for example in U.S. Patent 3,545,971 (Barnes et al.) and EP 0 248,390A1 (Akio et al.). Preferably, the black-and-white developing compositions used during processing are free of any photographic film hardeners, such as glutaraldehyde.

Radiographic kits can include a radiographic silver halide film or imaging assembly of this invention, one or more additional fluorescent intensifying screens and/or metal screens, and/or one or more suitable processing compositions (for example, black-and-white developing and fixing compositions).

The following examples are presented for illustration and the invention is not to be interpreted as limited thereby.

Example 1:

Radiographic Film A (Control):

Radiographic Film A was a dual-coated film having the two different silver halide emulsion layers on each side of a blue-tinted 170 μ m transparent poly(ethylene terephthalate) film support and an interlayer and overcoat layer over each emulsion layer. The emulsions of Film A were not prepared using oxidized gelatin.

Radiographic Film A had the following layer arrangement:

Overcoat

Interlayer

Emulsion Layer 1

Emulsion Layer 2

Support

Emulsion Layer 2

Emulsion Layer 1

Interlayer

Overcoat

5 The noted layers were prepared from the following formulations.

	<u>Overcoat Formulation</u>	<u>Coverage (mg/dm²)</u>
	Gelatin vehicle	3.4
	Methyl methacrylate matte beads	0.14
10	Carboxymethyl casein	0.57
	Colloidal silica (LUDOX AM)	0.57
	Polyacrylamide	0.57
	Chrome alum	0.025
	Resorcinol	0.058
15	Spermafol	0.15
	<u>Interlayer Formulation</u>	<u>Coverage (mg/dm²)</u>
	Gelatin vehicle	3.4
	Carboxymethyl casein	0.57
20	Colloidal silica (LUDOX AM)	0.57
	Polyacrylamide	0.57
	Chrome alum	0.025
	Resorcinol	0.058
	Nitron	0.044
25	<u>Emulsion Layer 1 Formulation</u>	<u>Coverage (mg/dm²)</u>
	Tabular grain emulsion	
	[AgBr 4.0 µm ave. dia. x 0.125 µm thickness]	12.9
	Gelatin vehicle	17.3
30	4-Hydroxy-6-methyl-1,3,3a,7-tetraazaindene	2.1 g/Ag mole
	Potassium nitrate	1.8

	Maleic acid hydrazide	0.0022
	Sorbitol	0.53
	Glycerin	0.57
	Potassium bromide	0.14
5	Resorcinol	0.44
	Bisvinylsulfonylmethane	2% based on total gelatin in all layers on that side

	<u>Emulsion Layer 2 Formulation</u>	<u>Coverage (mg/dm²)</u>
10	Tabular grain emulsion [AgBr 4.0 μ m ave. dia. x 0.125 μ m thickness]	6.5
	Gelatin vehicle	8.6
	5-Bromo-4-hydroxy-6-methyl-1,3,3a,7-tetraazaindene	0.7 g/Ag mole
15	Microcrystalline Dye M-1 (shown below)	1.08
	Potassium nitrate	1.1
	Ammonium hexachloropalladate	0.0013
	Maleic acid hydrazide	0.0053
	Sorbitol	0.32
20	Glycerin	0.35
	Potassium bromide	0.083
	Resorcinol	0.26
	Bisvinylsulfonylmethane	2% based on total gelatin in all layers on that side

M-1

5 Radiographic Film B (Invention):

Radiographic Film B was a dual-coated, symmetric radiographic film with two different silver halide emulsion layers on each side of the support. The two emulsion layers contained tabular silver halide grains that were prepared and dispersed in deionized oxidized gelatin that had been added at multiple times
 10 before and/or during the nucleation and early growth of the silver bromide tabular grains dispersed therein. The tabular grains of the innermost silver halide emulsion layers had a mean aspect ratio of about 35 and the tabular grains of the outermost silver halide emulsion layers had a mean aspect ratio of about 18. The nucleation and early growth of the tabular grains were performed using a
 15 "bromide-ion-concentration free-fall" process in which a dilute silver nitrate solution was slowly added to a bromide ion-rich deionized oxidized gelatin environment. The grains were chemically sensitized with sulfur, gold, and selenium using conventional procedures. Spectral sensitization to about 560 nm was provided using anhydro-5,5-dichloro-9-ethyl-3,3'-bis(3-
 20 sulfopropyl)oxacarbocyanine hydroxide (680 mg/mole of silver) followed by potassium iodide (400 mg/mole of silver).

Film B had the following layer arrangement and formulations on the film support:

	Overcoat	
	Interlayer	
	Emulsion Layer 1	
	Emulsion Layer 2	
5	Support	
	Emulsion Layer 2	
	Emulsion Layer 1	
	Interlayer	
	Overcoat	
10		
	<u>Overcoat Formulation</u>	<u>Coverage (mg/dm²)</u>

30

Samples of the films were exposed through a graduated density step tablet to a MacBeth sensitometer for 1/50th second to a 500 watt General

Electric DMX projector lamp calibrated to 2650°K, filtered with a Corning C4010 filter to simulate a green-emitting X-ray fluorescent intensifying screen.

The exposed film samples were processed using a commercially available KODAK RP X-OMAT® Film Processor M6A-N, M6B, or M35A.

- 5 Development was carried out using the following black-and-white developing composition:

	Hydroquinone	30 g
	Phenidone	1.5 g
10	Potassium hydroxide	21 g
	NaHCO ₃	7.5 g
	K ₂ SO ₃	44.2 g
	Na ₂ S ₂ O ₅	12.6 g
	Sodium bromide	35 g
15	5-Methylbenzotriazole	0.06 g
	Glutaraldehyde	4.9 g
	Water to 1 liter, pH 10	

- Fixing was carried out using KODAK RP X-OMAT® LO Fixer and
 20 Replenisher fixing composition (Eastman Kodak Company). The film samples were processed in each instance for less than 90 seconds (dry-to-dry).

- Optical densities are expressed below in terms of diffuse density as measured by a conventional X-rite Model 310TM densitometer that was calibrated to ANSI standard PH 2.19 and was traceable to a National Bureau of Standards
 25 calibration step tablet. The characteristic D vs. logE curve was plotted for each radiographic film that was exposed and processed as noted above. Film speed was normalized by designating the film speed of Film A as 400. A density vs. logE curve was generated for Film B to determine its film speed relative to Film A. Contrast (gamma) is the slope (derivative) of the density vs. logE sensitometric
 30 curve. The % crossover was measured using the procedure described above.

The following TABLE I shows the sensitometric data of Films A and B. The data show that Film B had increased photographic speed higher contrast, and D_{\max} , and decreased fog.

5

TABLE I

Film	Film Speed	Contrast	Fog	Crossover	D_{\max}
A (Control)	400	2.6	0.24	8%	3.1
B (Invention)	800	3.0	0.22	8%	3.8

The invention has been described in detail with particular reference to preferred embodiments thereof, but it will be understood that variations and modifications can be effected within the spirit and scope of the invention.
